*With inputs from conveners

Simplified models - forging path into unknown

- **Problem:** Too many new physics models - impossible to test all against experimental data
- **Proposal:** Parametrize new physics scenarios with few masses and couplings without loss of generality
 - Fixed production mechanism
 - Fixed decay modes
- **Outcome:**
 - Presentation of experimental search results
 - Identification of uncovered parameter space

[arXiv:1506.03116](https://arxiv.org/abs/1506.03116)

Simplified models - use cases

- Simplified models are everywhere
- **HL-LHC program** (extension of ongoing searches)
 - Is our susy simplified model program extensive? Do all simplified models make sense?
 - How can the DMWG program be extended in order to improve usability and scope?
- **Future colliders** (defining new physics benchmarks)
 - Given the expected results from HL-LHC, which new physics simplified model scenarios/benchmarks would be the most interesting to target?
- **Connecting different frontiers** (AF \leftrightarrow EF \leftrightarrow CF)
 - How do simplified models help us understand complementarity between different frontiers?
 - What are the pitfalls of such approaches? Would we end up over optimising anywhere?
- **Defining new simplified models for new new physics scenarios**
 - How do we go about exploring new new physics scenarios such as strongly interacting dark sectors and define associated simplified models which cover all possible experimental signatures?

SUSY simplified models

- Construction of simplified models from well defined high scale theory (MSSM)
- Three outcomes
 - **Exclusion lines** - give sense of progress, quick guesstimate
 - **Upper limits** - upper limits on production cross section $\sigma \times \text{BR}$, allow to quickly estimate feasibility of same $\sigma \times \text{BR}$ in theory scenarios
 - **Efficiency maps** - parametrize kinematics, allow to combine topologies, allow to use likelihoods
- Led to development of tools e.g. [SModelS](#), [FastLim](#)

Dark matter simplified models

- Construction of simplified models motivated by high scale theory models
 - Z' with arbitrary couplings, parameters $m_{Z'}$, m_{DM} , g_{DM} , g_q
- Can be used to **connect LHC and cosmic frontiers** (DMWG document [arXiv:1603.04156](https://arxiv.org/abs/1603.04156))
- **Work ongoing in EF10** to understand impact of assumptions on this plot
- **Limited use for reinterpretation purposes**
 - More later

LLP simplified models

- A mixture of well defined high scale theories and well motivated scenarios
- Demonstrate parameter space covered and uncovered by experiments
- Complementarity with lifetime frontier/forward experiments

See talk by [B. Shuve](#)

SM measurements and simplified models

- Turn absence of new physics signal into a precision measurement program
- Test SM EFT and theory simplified model predictions against SM precision measurements

See [CONTUR](#)

Simplified models - advantages

- Easy to use and understand
 - It is also important to put the LHC program in wider context, full models can be too complicated to understand for someone from outside the field, simplified models help communicate
- Easy to put different experiments on the same plane (DMWG)

- Easy to **compare our own progress** and search channels

May 2020

 $\sqrt{s} = 13 \text{ TeV}$ 

Simplified models - advantages (summary)

- Easy to handle experimentally
- Easy to compare our own progress
- Easy to evaluate dependence of quantum particle properties e.g. spin
- Reinterpretation (see also discussion in reinterpretation forum report [arXiv:2003.07868](https://arxiv.org/abs/2003.07868))
- Easy to use and understand
 - It is also important to put the LHC program in wider context, full models can be too complicated to understand for someone from outside the field, simplified models help communicate
- Easy to put different experiments on the same plane (DMWG)

Simplified models - disadvantages

- **Too conservative limits** - lead to false sense of abandonment
 - “Low scale susy is ruled out”
 - Contrary, light electroweak sector still very much alive

Simplified models - disadvantages

- Some simplified models can be **unrealistic**, or too fine tuned
 - Mono-W models violated unitarity
 - Topologies such as shown here (RHS) are too specific (and are considered by the experiments)

Artificial enhancement

Simplified models - disadvantages (summary)

- Too **conservative limits** - lead to false sense of abandonment
 - “*Low scale susy is ruled out*”
 - Contrary, light electroweak sector still very much alive
- Some simplified models can be **unrealistic**, or too fine tuned
 - Mono-W models violated unitarity
 - Topologies such as shown here (RHS) are too specific (and are considered by the experiments)
- Simplified models can lead to **limited signature space**
 - Higgs to susy final states e.g. discussed by [C. Wagner](#), [M. Carena](#) are possible only when considering both heavy Higgs and and electroweakino sectors
 - Long cascade decays in susy are not covered by existing simplified model topologies
 - Dark Higgs phenomenology in dark higgs dark photon models can be equally important

See talk by [M. Pospelov](#)

Simplified models - future directions

- Less simple simplified models - particularly useful for supersymmetry
- Upper limits vs/and efficiency maps
- DM WG going beyond mass coupling slices
See talk by [P. Harris](#), [B. Gao](#)
- Connecting DM@colliders and DM@accelerators (EF \leftrightarrow AF cross talk)
See talk by [N. Toro](#)
- Defining benchmarks for new scenarios - dark showers, LLP(ongoing), fixed target experiments (PBC report, for beyond see talk by [M. Pospelov](#))
 - Necessary to develop tools which will accept full model as input and predict simplified model topologies (SModelS does this for Z_2 conserving topologies, plans to extend)
- Simplified models and the EFT - in some limit simplified models and EFT can be matched onto each other
- Can we use simplified models to build full models?
- Simplified models for future colliders - too early to think about?

Conclusions

- Nature is likely not going to be simplified
- With low hanging fruits gone, we should start thinking about less simple simplified models
 - DMWG t-channel models
 - SUSY one step cascade decays
- We should be careful about drawing a boundary between simplified models and full models
- Don't abandon the current simplified models yet, they reflect continuation of previous LHC legacy results
 - Work in progress within to show impact of assumptions for DM simplified models
- Defining simplified models for new new physics scenarios e.g. strongly interacting dark sectors will require a community effort and it is extremely crucial
